Features

- High speed data transfer rates with system frequency up to 533MHz
- Posted CAS
- Programmable $\overline{CAS}$ Latency: 3, 4, 5, 6 and 7
- Programmable Additive Latency: 0, 1, 2, 3, 4, 5 and 6
- Write Latency = Read Latency -1
- Programmable Wrap Sequence: Sequential or Interleave
- Programmable Burst Length: 4 and 8
- Automatic and Controlled Precharge Command
- Power Down Mode
- Auto Refresh and Self Refresh
- Refresh Interval: 7.8 us at lower than Tcase 85°C, 3.9 us at 85°C < Tcase ≤ 95°C
- ODT (On-Die Termination)
- Weak Strength Data-Output Driver Option
- Bidirectional differential Data Strobe (Single-ended data-strobe is an optional feature)
- On-Chip DLL aligns DQ and DQs transitions with CK transitions
- Differential clock inputs CK and $\overline{CK}$
- JEDEC Power Supply 1.8V ± 0.1V
- Available in 60-ball FBGA for x8 component or 84 ball FBGA for x16 component
- All inputs & outputs are compatible with SSTL_18 interface
- tRAS lockout supported
- Read Data Strobe supported (x8 only)
- Internal four bank operations with single pulsed RAS

Description

The D59C1512(804/164)QE is a four bank DDR DRAM organized as 4 banks x 16Mbit x 8 (804) or 4 banks x 8Mbit x 16 (164). The V59C1512(804/164)QE achieves high speed data transfer rates by employing a chip architecture that prefetches multiple bits and then synchronizes the output data to a system clock.

The chip is designed to comply with the following key DDR2 SDRAM features: (1) posted CAS with additive latency, (2) write latency = read latency -1, (3) On Die Termination.

All of the control, address, circuits are synchronized with the positive edge of an externally supplied clock. I/Os are synchronized with a pair of bidirectional strobes (DQS, $\overline{DQS}$) in a source synchronous fashion.

Operating the four memory banks in an interleaved fashion allows random access operation to occur at a higher rate than is possible with standard DRAMs. A sequential and gapless data rate is possible depending on burst length, CAS latency and speed grade of the device.

Available Speed Grade:

- 37 (DDR2-533) @ CL 4-4-4
- 3 (DDR2-667) @ CL 5-5-5
- 25A (DDR2-800) @ CL 6-6-6
- 25 (DDR2-800) @ CL 5-5-5
- 19A(DDR2-1066)@CL 7-7-7

Notes:

1. Pins B3 and A2 have identical capacitance as pins B7 and A8.
2. For a read, when enabled, strobe pair RDQS & RDQS are identical in function and timing to strobe pair DQS & DQS and input masking function is disabled.
3. The function of DM or RDQS/RDQS are enabled by EMRS command.
4. VDDL and VSSDL are power and ground for the DLL. It is recommended that they are isolated on the device from VDD, VDDQ, VSS, and VSSQ.

Signal Pin Description

Pin	Type	Function
CK, $\overline{\text{CK}}$	Input	The system clock input. All inputs except DQs and DMs are sampled on the rising edge of CK.
CKE	Input	Activates the CK signal when high and deactivates the CK signal when low, thereby initiates either the Power Down mode, or the Self Refresh mode.
$\overline{\text{CS}}$	Input	$\overline{\text{CS}}$ enables the command decoder when low and disables the command decoder when high. When the command decoder is disabled, new commands are ignored but previous operations continue.
$\overline{\text{RAS}}$, $\overline{\text{CAS}}$, $\overline{\text{WE}}$	Input	When sampled at the positive rising edge of the clock, $\overline{\text{CAS}}$, $\overline{\text{RAS}}$, and $\overline{\text{WE}}$ define the command to be executed by the SDRAM.
A0 - A13	Input	During a Bank Activate command cycle, A0-A13 defines the row address (RA0-RA13) when sampled at the rising clock edge for x8 and A0-A12 row address for x16 device. During a Read or Write command cycle, A0-An defines the column address (CA0-CAn) when sampled at the rising clock edge. CAn depends on the SDRAM organization: 64M x 8 DDR CAn = CA9 32M x 16 DDR CAn = CA9 In addition to the column address, A10 (= AP) is used to invoke autoprecharge operation at the end of the burst read or write cycle. If A10 is high, autoprecharge is selected and BA0, BA1 defines the bank to be precharged. If A10 is low, autoprecharge is disabled. During a Precharge command cycle, A10 (= AP) is used in conjunction with BA0 and BA1 to control which bank(s) to precharge. If A10 is high, all four banks will be precharged simultaneously regardless of state of BA0 and BA1.
BA0, BA1	Input	Selects which bank is to be active.
DQx	Input/ Output	Data Input/Output pins operate in the same manner as on conventional DRAMs. DQ0-DQ7 for x8 component and DQ0-DQ15 for x16 component.
DQS, ($\overline{\text{DQS}}$) LDQS, ($\overline{\text{LDQS}}$) UDQS, ($\overline{\text{UDQS}}$) RDQS, ($\overline{\text{RDQS}}$)	Input/ Output	Data Strobe, output with read data, input with write data. Edge-aligned with read data, centered in write data. For x16 device, LDQS corresponds to the data on DQ0-DQ7; UDQS corresponds to the data on DQ8-DQ15. For x8 device, an RDQS option using DM pin can be enabled via the EMRS(1) to simplify read timing. The data strobes DQS, LDQS, UDQS, and RDQS may be used in single ended mode or paired with optional complimentary signals $\overline{\text{DQS}}$, $\overline{\text{LDQS}}$, $\overline{\text{UDQS}}$, and $\overline{\text{RDQS}}$ to provide differential pair signaling to the system during both reads and writes. An EMRS(1) control bit enables or disables all complementary data strobe signals. In this data sheet, "differential DQS signals" refers to any of the following with A10 = 0 of EMRS(1) x8 DQS/$\overline{\text{DQS}}$ if EMRS(1)[A11] = 0 x8 DQS/$\overline{\text{DQS}}$, RDQS/$\overline{\text{RDQS}}$ if EMRS(1)[A11] = 1 x16 LDQS/$\overline{\text{LDQS}}$ and UDQS/$\overline{\text{UDQS}}$ "single-ended DQS signals" refers to any of the following with A10 = 1 of EMRS(1) x8 DQS if EMRS(1)[A11] = 0 x8 DQS, RDQS, if EMRS(1)[A11] = 1 x16LDQS and UDQS

DM, LDM,UDM	Input	DM is an input mask signal for write data. Input data is masked when DM is sampled high along with that input data during a Write access. DM is sampled on both edges of DQS. Although DM pins are input only, the DM loading is designed to match that of DQ and DQS pins. For x8 device, the function of DM or RDQS/RDQS is enabled by EMRS command. For x16 device, LDM is DM for lower byte DQ0-DQ7 and UDM is DM for upper byte DQ8-DQ15.
VDD, VSS	Supply	Power and ground for the input buffers and the core logic.
VDDQ, VSSQ	Supply	Isolated power supply and ground for the output buffers to provide improved noise immunity.
VREF	Input	SSTL Reference Voltage for Inputs
VDDL, VSSDL	Supply	Isolated power supply and ground for the DLL to provide improved noise immunity.
ODT	Input	On Die Termination Enable. It enables termination resistance internal to the DRAM. ODT is applied to each DQ, DQS, $\overline{\text{DQS}}$, RDQS, $\overline{\text{RDQS}}$ and DM for x8 device. For x16 configuration ODT is applied to each DQ, UDQS/ $\overline{\text{UDQS}}$, LDQS/ $\overline{\text{LDQS}}$, UDM and LDM signal. ODT will be ignored if EMRS disable the function.

Simplified State Diagram

Basic Functionality

Read and write accesses to the DDR2 SDRAM are burst oriented; accesses start at a selected location and continue for a burst length of four or eight in a programmed sequence. Accesses begin with the registration of an Active command, which is then followed by a Read or Write command. The address bits registered coincident with the active command are used to select the bank and row to be accessed (BA0, BA1 select the bank; A0-A13 select the row). The address bits registered coincident with the Read or Write command are used to select the starting column location for the burst access and to determine if the auto precharge command is to be issued.

Prior to normal operation, the DDR2 SDRAM must be initialized. The following sections provide detailed information covering device initialization, register definition, command descriptions and device operation.

Power up and Initialization

DDR2 SDRAMs must be powered up and initialized in a predefined manner. Operational procedures other than those specified may result in undefined operation.

Power-up and Initialization Sequence

The following sequence is required for POWER UP and Initialization.

1. Apply power and attempt to maintain CKE below $0.2 \cdot V_{DDQ}$ and ODT^{*1} at a low state (all other inputs may be undefined.)
 - VDD, VDDL and VDDQ are driven from a single power converter output, AND
 - VTT is limited to 0.95V max, AND
 - Vref tracks $V_{DDQ}/2$.or
 - Apply VDD before or at the same time as VDDL.
 - Apply VDDL before or at the same time as VDDQ.
 - Apply VDDQ before or at the same time as VTT & Vref.at least one of these two sets of conditions must be met.
2. Start clock and maintain stable condition.
3. For the minimum of 200us after stable power and clock (CK, $\overline{CK}$), then apply NOP or deselect & take CKE high.
4. Wait minimum of 400ns then issue precharge all command. NOP or deselect applied during 400ns period.
5. Issue EMRS(2) command. (To issue EMRS(2) command, provide "Low" to BA0, "High" to BA1.)
6. Issue EMRS(3) command. (To issue EMRS(3) command, provide "High" to BA0 and BA1.)
7. Issue EMRS to enable DLL. (To issue "DLL Enable" command, provide "Low" to A0, "High" to BA0 and "Low" to BA1 and A12.)
8. Issue a Mode Register Set command for "DLL reset".
(To issue DLL reset command, provide "High" to A8 and "Low" to BA0-1)
9. Issue precharge all command.
10. Issue 2 or more auto-refresh commands.
11. Issue a mode register set command with low to A8 to initialize device operation. (i.e. to program operating parameters without resetting the DLL.
12. At least 200 clocks after step 8, EMRS OCD Default command (A9=A8= A7=1) followed by EMRS OCD Exit command (A9=A8=A7=0) must be issued with other operating parameters of EMRS.

13. The DDR2 SDRAM is now ready for normal operation.

*1) To guarantee ODT off, VREF must be valid and a low level must be applied to the ODT pin.

Initialization Sequence after Power Up

Programming the Mode Register

For application flexibility, burst length, burst type, $\overline{\text{CAS}}$ latency, DLL reset function, write recovery time (tWR) are user defined variables and must be programmed with a Mode Register Set (MRS) command. Additionally, DLL disable function, driver impedance, additive CAS latency, single-ended strobe and ODT (On Die Termination) are also user defined variables and must be programmed with an Extended Mode Register Set (EMRS) command. Contents of the Mode Register (MR) or Extended Mode Registers (EMR(#)) can be altered by re-executing the MRS and EMRS Commands. If the user chooses to modify only a subset of the MRS or EMRS variables, all variables must be redefined when the MRS or EMRS commands are issued.

MRS, EMRS and Reset DLL do not affect array contents, which means reinitialization including those can be executed any time after power-up without affecting array contents.

DDR2 SDRAM Mode Register Set (MRS)

The mode register stores the data for controlling the various operating modes of DDR2 SDRAM. It controls CAS latency, burst length, burst sequence, test mode, DLL reset, tWR and various vendor specific options to make DDR2 SDRAM useful for various applications. The default value of the mode register is not defined, therefore the mode register must be written after power-up for proper operation. The mode register is written by asserting low on CS, RAS, CAS, WE, BA0 and BA1, while controlling the state of address pins A0 ~ A15. The DDR2 SDRAM should be in all bank precharge with CKE already high prior to writing into the mode register. The mode register set command cycle time (tMRD) is required to complete the write operation to the mode register. The mode register contents can be changed using the same command and clock cycle requirements during normal operation as long as all banks are in the precharge state. The mode register is divided into various fields depending on functionality. Burst length is defined by A0 ~ A2 with options of 4 and 8 bit burst lengths. The burst length decodes are compatible with DDR SDRAM. Burst address sequence type is defined by A3, CAS latency is defined by A4 ~ A6. The DDR2 doesn't support half clock latency mode. A7 is used for test mode. A8 is used for DLL reset. A7 must be set to low for normal MRS operation. Write recovery time tWR is defined by A9 ~ A11. Refer to the table for specific codes.

*1 : A13 is reserved for future use and must be programmed to 0 when setting the mode register.

BA2 and A14 are not used for 512Mb, but used for 1Gb and 2Gb DDR2 SDRAMs. A15 is reserved for future usage.

*2 : WR(write recovery for autprecharge) min is determined by tCK max and WR max is determined by tCK min. WR in clock cycles is calculated by dividing tWR (in ns) by tCK (in ns) and rounding up a non-integer value to the next integer (WR[cycles] = tWR(ns)/tCK(ns)). The mode register must be programmed to this value. This is also used with tRP to determine tDAL.

DDR2 SDRAM Extended Mode Register Set

EMRS(1)

The extended mode register(1) stores the data for enabling or disabling the DLL, output driver strength, ODT value selection and additive latency. The default value of the extended mode register is not defined, therefore the extended mode register must be written after power-up for proper operation. The extended mode register is written by asserting low on $\overline{CS}$, $\overline{RAS}$, $\overline{CAS}$, $\overline{WE}$ and high on BA0, while controlling the states of address pins A0 ~ A13. The DDR2 SDRAM should be in all bank precharge with CKE already high prior to writing into the extended mode register. The mode register set command cycle time (tMRD) must be satisfied to complete the write operation to the extended mode register. Mode register contents can be changed using the same command and clock cycle requirements during normal operation as long as all banks are in the pre-charge state. A0 is used for DLL enable or disable. A1 is used for enabling a half strength data-output driver. A3~A5 determines the additive latency, A2 and A6 are used for ODT value selection, A7~A9 are used for OCD control, A10 is used for DQS# disable and A11 is used for RDQS enable.

DLL Enable/Disable

The DLL must be enabled for normal operation. DLL enable is required during power up initialization, and upon returning to normal operation after having the DLL disabled. The DLL is automatically disabled when entering self refresh operation and is automatically re-enabled upon exit of self refresh operation. Any time the DLL is enabled (and subsequently reset), 200 clock cycles must occur before a Read command can be issued to allow time for the internal clock to be synchronized with the external clock. Failing to wait for synchronization to occur may result in a violation of the tAC or tDQSCK parameters.

EMRS(1) Programming

*1 : A13 is reserved for future use and must be programmed to 0 when setting the mode register.
BA2 and A14 are not used for 512Mb, but used for 1Gb and 2Gb DDR2 SDRAMs. A15 is reserved for future use.

*2 : Optional for DDR2-400/533/667/800/1066

EMRS(2) Programming: ^{*1}

*1: All bits except A7, BA0 and BA1 must be programmed to 0 when setting the mode register during initialization.

*2: BA2 and A14 are not used for 512Mb, but used for 1Gb and 2Gb DDR2 SDRAMs. A15 is reserved for future usage.

EMRS(3) Programming: Reserved ^{*1}

*1: EMRS(3) is reserved for future use and all bits except BA0 and BA1 must be programmed to 0 when setting the mode register during initialization.

*2: BA2 and A14 are not used for 512Mb, but used for 1Gb and 2Gb DDR2 SDRAMs. A15 is reserved for future usage.

On-Die Termination (ODT)

ODT (On-Die Termination) is a new feature on DDR2 components that allows a DRAM to turn on/off termination resistance for each DQ, DQS, $\overline{DQS}$, DM, RDQS (DM and RDQS share the same pin) and $\overline{RDQS}$ for x8 configuration via the ODT control pin, where $\overline{DQS}$ is terminated only when enabled in the EMRS by address bit A10 = 0. For x8 configuration, RDQS is only terminated, when enabled in the EMRS by address bits A10 = 0 and A11 = 1.

For x16 configuration, ODT is applied to each DQ, UDQS, $\overline{UDQS}$, LDQS, $\overline{LDQS}$, UDM and LDM signal via the ODT control pin, where UDQS and LDQS are terminated only when enabled in the EMRS by address bit A10 = 0.

The ODT feature is designed to improve signal integrity of the memory channel by allowing the DRAM controller to independently turn on/off termination resistance for any or all DRAM devices.

The ODT function can be used for all active and standby modes. ODT is turned off and not supported in Self-Refresh mode.

Functional Representation of ODT

Switch SW1 or SW2 is enabled by the ODT pin.

Selection between SW1 or SW2 is determined by "Rtt (nominal)" in EMRS address bits A6 & A2.

Target $R_{tt} = 0.5 \times R_{val1}$ or $0.5 \times R_{val2}$.

The ODT pin will be ignored if the Extended Mode Register (EMRS) is programmed to disable ODT.

ODT Truth Tables

The ODT Truth Table shows which of the input pins are terminated depending on the state of address bit A10 and A11 in the EMRS.

To activate termination of any of these pins, the ODT function has to be enabled in the EMRS by address bits A6 and A2.

Input Pin	EMRS Address Bit A10	EMRS Address Bit A11
x8 components :		
DQ0~DQ7	X	X
DQS	X	X
$\overline{\text{DQS}}$	0	X
RDQS	X	1
$\overline{\text{RDQS}}$	0	1
DM	X	0
x16 components :		
DQ0~DQ7	X	X
DQ8~DQ15	X	X
LDQS	X	X
$\overline{\text{LDQS}}$	0	X
UDQS	X	X
$\overline{\text{UDQS}}$	0	X
LDM	X	X
UDM	X	X

X=Don't Care
 0=Signal Low
 1=Signal High

DC Electrical Characteristics and Operation Conditions:

Parameter / Condition	Symbol	min.	nom.	max.	Units	Notes
Rtt eff. impedance value for EMRS(A6,A2)=0,1; 75 ohm	Rtt1(eff)	60	75	90	ohm	1
Rtt eff. impedance value for EMRS(A6,A2)=0,1; 150 ohm	Rtt2(eff)	120	150	180	ohm	1
Rtt eff. impedance value for EMRS(A6,A2)=1,1; 50ohm	Rtt3(eff)	40	50	60	ohm	1,3
Deviation of VM with respect to VDDQ/2	delta VM	-6		+6	%	2

1) Measurement Definition for Rtt(eff) :

Apply VIHac and VILac to test pin seperately, then measure current I(VIHac) and I(VILac) respectively

$$Rtt(eff) = (VIHac - VILac) / (I(VIHac) - I(VILac))$$

2) Measurement Definition for VM :

Measure voltage (VM) at test pin (midpoint) with no load:

$$\text{delta VM} = ((2 * VM / VDDQ) - 1) \times 100\%$$

3) Optional for DDR2-400/533/667/800/1066

AC Electrical Characteristics and Operation Conditions: For speed 533

Symbol	Parameter / Condition	min.	max.	Units	Notes
tAOND	ODT turn-on delay	2	2	tCK	
tAON	ODT turn-on	tAC(min)	tAC(max) + 1ns	ns	1
tAONPD	ODT turn-on (Power-Down Mode)	tAC(min) + 2ns	2 tCK + tAC(max) + 1ns	ns	3
tAOFD	ODT turn-off delay	2.5	2.5	tCK	
tAOF	ODT turn-off	tAC(min)	tAC(max) + 0.6ns	ns	2
tAOFPD	ODT turn-off (Power-Down Mode)	tAC(min) + 2ns	2.5 tCK + tAC(max) + 1ns	ns	3
tANPD	ODT to Power Down Mode Entry Latency	3		tCK	4
tAXPD	ODT Power Down Exit Latency	8		tCK	4

1) ODT turn on time min. is when the device leaves high impedance and ODT resistance begins to turn on.
ODT turn on time max. is when the ODT resistance is fully on. Both are measured from tAOND.

2) ODT turn off time min. is when the device starts to turn-off ODT resistance.
ODT turn off time max. is when the bus is in high impedance. Both are measured from tAOFD.

3) For Standard Active Power-down - with MRS A12 ="0" - the non power-down timings (tAOND, tAON, tAOFD and tAOF) apply

4) tANPD and tAXPD define the timing limit when either Power Down Mode Timings (tAONPD, tAOFPD) or Non-Power Down Mode timings (tAOND, tAOFD) have to be applied.

AC Electrical Characteristics and Operation Conditions: For speed 667/800

Symbol	Parameter / Condition	min.	max.	Units	Notes
t _{AOND}	ODT turn-on delay	2	2	t _{CK}	
t _{AON}	ODT turn-on	t _{AC} (min)	t _{AC} (max) + 0.7ns	ns	1
t _{AONPD}	ODT turn-on (Power-Down Mode)	t _{AC} (min) + 2ns	2 t _{CK} + t _{AC} (max) + 1ns	ns	3
t _{AOFD}	ODT turn-off delay	2.5	2.5	t _{CK}	
t _{AOF}	ODT turn-off	t _{AC} (min)	t _{AC} (max) + 0.6ns	ns	2
t _{AOFPD}	ODT turn-off (Power-Down Mode)	t _{AC} (min) + 2ns	2.5 t _{CK} + t _{AC} (max) + 1ns	ns	3
t _{ANPD}	ODT to Power Down Mode Entry Latency	3	X	t _{CK}	4
t _{AXPD}	ODT Power Down Exit Latency	8		t _{CK}	4

- 1) ODT turn on time min. is when the device leaves high impedance and ODT resistance begins to turn on.
ODT turn on time max. is when the ODT resistance is fully on. Both are measured from t_{AOND}.
- 2) ODT turn off time min. is when the device starts to turn-off ODT resistance.
ODT turn off time max. is when the bus is in high impedance. Both are measured from t_{AOFD}.
- 3) For Standard Active Power-down - with MRS A12 = "0" - the non power-down timings (t_{AOND}, t_{AON}, t_{AOFD} and t_{AOF}) apply
- 4) t_{ANPD} and t_{AXPD} define the timing limit when either Power Down Mode Timings (t_{AONPD}, t_{AOFPD}) or Non-Power Down Mode timings (t_{AOND}, t_{AOFD}) have to be applied.

AC Electrical Characteristics and Operation Conditions: For speed 1066

Symbol	Parameter / Condition	min.	max.	Units	Notes
t _{AOND}	ODT turn-on delay	2	2	t _{CK}	
t _{AON}	ODT turn-on	t _{AC} (min)	t _{AC} (max) + 2.575	ns	1
t _{AONPD}	ODT turn-on (Power-Down Mode)	t _{AC} (min) + 2ns	3 t _{CK} + t _{AC} (max) + 1ns	ns	3
t _{AOFD}	ODT turn-off delay	2.5	2.5	t _{CK}	
t _{AOF}	ODT turn-off	t _{AC} (min)	t _{AC} (max) + 0.6ns	ns	2
t _{AOFPD}	ODT turn-off (Power-Down Mode)	t _{AC} (min) + 2ns	2.5 t _{CK} + t _{AC} (max) + 1ns	ns	3
t _{ANPD}	ODT to Power Down Mode Entry Latency	4	X	t _{CK}	4
t _{AXPD}	ODT Power Down Exit Latency	11		t _{CK}	4

- 1) ODT turn on time min. is when the device leaves high impedance and ODT resistance begins to turn on.
ODT turn on time max. is when the ODT resistance is fully on. Both are measured from t_{AOND}.
- 2) ODT turn off time min. is when the device starts to turn-off ODT resistance.
ODT turn off time max. is when the bus is in high impedance. Both are measured from t_{AOFD}.
- 3) For Standard Active Power-down - with MRS A12 = "0" - the non power-down timings (t_{AOND}, t_{AON}, t_{AOFD} and t_{AOF}) apply
For t_{AONPD}(max) DDR1066 it's 3t_{CK}+t_{AC}(max)+1ns
- 4) t_{ANPD} and t_{AXPD} define the timing limit when either Power Down Mode Timings (t_{AONPD}, t_{AOFPD}) or Non-Power Down Mode timings (t_{AOND}, t_{AOFD}) have to be applied.

ODT Timing for Active / Standby (Idle) Mode and Standard Active Power-Down Mode

ODT Timing for Precharge Power-Down and Low Power Power-Down Mode

Bank Activate Command

The Bank Activate command is issued by holding $\overline{\text{CAS}}$ and $\overline{\text{WE}}$ high with $\overline{\text{CS}}$ and $\overline{\text{RAS}}$ low at the rising edge of the clock. The bank addresses of BA0 - BA2 are used to select the desired bank. The row addresses A0 through A13 are used to determine which row to activate in the selected bank for x8 organised components. For x16 components, row addresses A0 through A12 have to be applied.

The Bank Activate command must be applied before any Read or Write operation can be executed. Immediately after the bank active command, the DDR2 SDRAM can accept a read or write command (with or without Auto-Precharge) on the following clock cycle. If a R/W command is issued to a bank that has not satisfied the t_{RCDmin} specification, then additive latency must be programmed into the device to delay the R/W command which is internally issued to the device. The additive latency value must be chosen to assure t_{RCDmin} is satisfied. Additive latencies of 0,1,2,3,4,5 and 6 are supported.

Once a bank has been activated, it must be precharged before another Bank Activate command can be applied to the same bank. The bank active and precharge times are defined as t_{RAS} and t_{RP} respectively. The minimum time interval between successive Bank Activate commands to the same bank is determined (t_{RC}). The minimum time interval between Bank Activate commands, to any other bank, is the Bank A to Bank B delay time (t_{RRD}).

Bank Activate Command Cycle: $t_{\text{RCD}} = 3$, $\text{AL} = 2$, $t_{\text{RP}} = 3$, $t_{\text{RRD}} = 2$

Read and Write Commands and Access Modes

After a bank has been activated, a read or write cycle can be executed. This is accomplished by setting $\overline{\text{RAS}}$ high, $\overline{\text{CS}}$ and $\overline{\text{CAS}}$ low at the clock's rising edge. $\overline{\text{WE}}$ must also be defined at this time to determine whether the access cycle is a read operation ($\overline{\text{WE}}$ high) or a write operation ($\overline{\text{WE}}$ low). The DDR2 SDRAM provides a wide variety of fast access modes. The boundary of the burst cycle is restricted to specific segments of the page length.

A new burst access must not interrupt the previous 4 bit burst operation in case of $\text{BL} = 4$ setting. Therefore the minimum $\overline{\text{CAS}}$ to $\overline{\text{CAS}}$ delay (t_{CCD}) is a minimum of 2 clocks for read or write cycles.

For 8 bit burst operation ($\text{BL} = 8$) the minimum $\overline{\text{CAS}}$ to $\overline{\text{CAS}}$ delay (t_{CCD}) is 4 clocks for read or write cycles. Burst interruption is allowed with 8 bit burst operation. For details see the "Burst Interrupt" - Section of this datasheet.

Read Burst Timing Example : (CL = 3, AL = 0, RL = 3, BL = 4)

Posted $\overline{\text{CAS}}$

Posted $\overline{\text{CAS}}$ operation is supported to make command and data bus efficient for sustainable bandwidths in DDR2 SDRAM. In this operation, the DDR2 SDRAM allows a $\overline{\text{CAS}}$ read or write command to be issued immediately after the $\overline{\text{RAS}}$ bank activate command (or any time during the $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$ delay time, t_{RCD} , period). The command is held for the time of the Additive Latency (AL) before it is issued inside the device. The Read Latency (RL) is controlled by the sum of AL and the $\overline{\text{CAS}}$ latency (CL). Therefore if a user chooses to issue a R/W command before the t_{RCDmin} , then AL (greater than 0) must be written into the EMRS(1). The Write Latency (WL) is always defined as $\text{RL} - 1$ (read latency - 1) where read latency is defined as the sum of additive latency plus $\overline{\text{CAS}}$ latency ($\text{RL} = \text{AL} + \text{CL}$). Read or Write operations using AL allow seamless bursts (refer to seamless operation timing diagram examples in Read burst and Write burst section).

Example 1: Read followed by a write to the same bank,
 where $\text{AL} = 2$ and $\text{CL} = 3$, $\text{RL} = (\text{AL} + \text{CL}) = 5$, $\text{WL} = (\text{RL} - 1) = 4$, $\text{BL} = 4$

Example 2: Read followed by a write to the same bank,
 where $\text{AL} = 0$ and $\text{CL} = 3$, $\text{RL} = (\text{AL} + \text{CL}) = 3$, $\text{WL} = (\text{RL} - 1) = 2$, $\text{BL} = 4$

Burst Mode Operation

Burst mode operation is used to provide a constant flow of data to memory locations (write cycle), or from memory locations (read cycle). The parameters that define how the burst mode will operate are burst sequence and burst length. The DDR2 SDRAM supports 4 bit and 8 bit burst modes only. For 8 bit burst-mode, full interleave address ordering is supported, however, sequential address ordering is nibble based for ease of implementation. The burst length is programmable and defined by the addresses A0 ~ A2 of the MRS. The burst type, either sequential or interleaved, is programmable and defined by the address bit 3 (A3) of the MRS. Seamless burst read or write operations are supported. Interruption of a burst read or write operation is prohibited, when burst length = 4 is programmed. For burst interruption of a read or write burst when burst length = 8 is used, see the “Burst Interruption” section of this datasheet. A Burst Stop command is not supported on DDR2 SDRAM devices.

Burst Length and Sequence

Burst Length	Starting Address (A2 A1 A0)	Sequential Addressing (decimal)	Interleave Addressing (decimal)
4	x 0 0	0, 1, 2, 3	0, 1, 2, 3
	x 0 1	1, 2, 3, 0	1, 0, 3, 2
	x 1 0	2, 3, 0, 1	2, 3, 0, 1
	x 1 1	3, 0, 1, 2	3, 2, 1, 0
8	0 0 0	0, 1, 2, 3, 4, 5, 6, 7	0, 1, 2, 3, 4, 5, 6, 7
	0 0 1	1, 2, 3, 0, 5, 6, 7, 4	1, 0, 3, 2, 5, 4, 7, 6
	0 1 0	2, 3, 0, 1, 6, 7, 4, 5	2, 3, 0, 1, 6, 7, 4, 5
	0 1 1	3, 0, 1, 2, 7, 4, 5, 6	3, 2, 1, 0, 7, 6, 5, 4
	1 0 0	4, 5, 6, 7, 0, 1, 2, 3	4, 5, 6, 7, 0, 1, 2, 3
	1 0 1	5, 6, 7, 4, 1, 2, 3, 0	5, 4, 7, 6, 1, 0, 3, 2
	1 1 0	6, 7, 4, 5, 2, 3, 0, 1	6, 7, 4, 5, 2, 3, 0, 1
	1 1 1	7, 4, 5, 6, 3, 0, 1, 2	7, 6, 5, 4, 3, 2, 1, 0

Note: 1) Page length is a function of I/O organization and column addressing.

2) Order of burst access for sequential addressing is “nibble-based” and therefore different from SDR or DDR components.

Burst Read Command

The Burst Read command is initiated by having $\overline{CS}$ and $\overline{CAS}$ low while holding $\overline{RAS}$ and $\overline{WE}$ high at the rising edge of the clock. The address inputs determine the starting column address for the burst. The delay from the start of the command until the data from the first cell appears on the outputs is equal to the value of the read latency (RL). The data strobe output (DQS) is driven low one clock cycle before valid data (DQ) is driven onto the data bus. The first bit of the burst is synchronized with the rising edge of the data strobe (DQS). Each subsequent data-out appears on the DQ pin in phase with the DQS signal in a source synchronous manner. The RL is equal to an additive latency (AL) plus $\overline{CAS}$ latency (CL). The CL is defined by the Mode Register Set (MRS). The AL is defined by the Extended Mode Register Set (EMRS).

Basic Burst Read Timing

Burst Read Operation: RL = 5 (AL = 2, CL = 3, BL = 4)

Burst Read Operation: RL = 3 (AL = 0, CL = 3, BL = 8)

Burst Read followed by Burst Write : RL = 5, WL = (RL-1) = 4, BL = 4

The minimum time from the burst read command to the burst write command is defined by a read-to-write turn-around time, which is $BL/2 + 2$ clocks.

Seamless Burst Read Operation : RL = 5, AL = 2, CL = 3, BL = 4

The seamless burst read operation is supported by enabling a read command at every BL / 2 number of clocks. This operation is allowed regardless of same or different banks as long as the banks are activated.

Seamless Burst Read Operation : RL = 3, AL = 0, CL = 3, BL = 8 (non interrupting)

The seamless, non interrupting 8-bit burst read operation is supported by enabling a read command at every BL / 2 number of clocks. This operation is allowed regardless of same or different banks as long as the banks are activated.

Burst Write Command

The Burst Write command is initiated by having $\overline{CS}$, $\overline{CAS}$ and $\overline{WE}$ low while holding $\overline{RAS}$ high at the rising edge of the clock. The address inputs determine the starting column address. Write latency (WL) is defined by a read latency (RL) minus one and is equal to $(AL + CL - 1)$. A data strobe signal (DQS) should be driven low (preamble) one clock prior to the WL. The first data bit of the burst cycle must be applied to the DQ pins at the first rising edge of the DQS following the preamble. The t_{DQSS} specification must be satisfied for write cycles. The subsequent burst bit data are issued on successive edges of the DQS until the burst length is completed. When the burst has finished, any additional data supplied to the DQ pins will be ignored. The DQ signal is ignored after the burst write operation is complete. The time from the completion of the burst write to bank precharge is named "write recovery time" (t_{WR}) and is the time needed to store the write data into the memory array. t_{WR} is an analog timing parameter (see the AC table in this specification) and is not the programmed value for WR in the MRS.

Basic Burst Write Timing

Burst Write Operation : RL = 5 (AL = 2, CL = 3), WL = 4, BL = 4

BW543

Burst Write Operation : RL = 3 (AL = 0, CL = 3), WL = 2, BL = 4

Burst Write followed by Burst Read : RL = 5 (AL = 2, CL = 3), WL = 4, tWTR = 2, BL = 4

The minimum number of clocks from the burst write command to the burst read command is

$$(CL - 1) + BL/2 + tWTR$$

where tWTR is the write-to-read turn-around time tWTR expressed in clock cycles. The tWTR is not a write recovery time (tWR) but the time required to transfer 4 bit write data from the input buffer into sense amplifiers in the array.

Seamless Burst Write Operation: RL=5, WL=4, BL=4

The seamless burst write operation is supported by enabling a write command every BL / 2 number of clocks. This operation is allowed regardless of same or different banks as long as the banks are activated.

Seamless Burst Write Operation: RL=3, WL=2, BL=8, noninterrupting

The seamless, non interrupting 8-bit burst write operation is supported by enabling a write command at every BL / 2 number of clocks. This operation is allowed regardless of same or different banks as long as the banks are activated.

Write Data Mask

One write data mask input (DM) for x8 components and two write data mask inputs (LDM, UDM) for x16 components are supported on DDR2 SDRAMs, consistent with the implementation on DDR SDRAMs. It has identical timings on write operations as the data bits, and though used in a uni-directional manner, is internally loaded identically to data bits to insure matched system timing. Data mask is not used during read cycles. If DM is high during a write burst coincident with the write data, the write data bit is not written to the memory. For x8 components the DM function is disabled, when RDQS / $\overline{\text{RDQS}}$ are enabled by EMRS.

Write Data Mask Timing

Burst Write Operation with Data Mask : RL = 3 (AL = 0, CL = 3), WL = 2, tWR = 3 , BL = 4

Burst Interruption

Interruption of a read or write burst is prohibited for burst length of 4 and only allowed for burst length of 8 under the following conditions:

1. A Read Burst of 8 can only be interrupted by another Read command. Read burst interruption by a Write or Precharge Command is prohibited.
2. A Write Burst of 8 can only be interrupted by another Write command. Write burst interruption by a Read or Precharge Command is prohibited.
3. Read burst interrupt must occur exactly two clocks after the previous Read command. Any other Read burst interrupt timings are prohibited.
4. Write burst interrupt must occur exactly two clocks after the previous Write command. Any other Read burst interrupt timings are prohibited.
5. Read or Write burst interruption is allowed to any bank inside the DDR2 SDRAM.
6. Read or Write burst with Auto-Precharge enabled is not allowed to be interrupted.
7. Read burst interruption is allowed by a Read with Auto-Precharge command.
8. Write burst interruption is allowed by a Write with Auto-Precharge command.
9. All command timings are referenced to burst length set in the mode register. They are not referenced to the actual burst. For example, Minimum Read to Precharge timing is $AL + BL/2$ where BL is the burst length set in the mode register and not the actual burst (which is shorter because of interrupt). Minimum Write to Precharge timing is $WL + BL/2 + tWR$, where tWR starts with the rising clock after the un-interrupted burst end and not from the end of the actual burst end.

Read Burst Interrupt Timing Example : (CL = 3, AL = 0, RL = 3, BL = 8)

Write Burst Interrupt Timing Example : (CL = 3, AL = 0, WL = 2, BL = 8)

Precharge Command

The Precharge Command is used to precharge or close a bank that has been activated. The Precharge Command is triggered when CS, RAS and WE are low and CAS is high at the rising edge of the clock. The Precharge Command can be used to precharge each bank independently or all banks simultaneously. Three address bits A10, BA1 and BA0 are used to define which bank to precharge when the command is issued.

Bank Selection for Precharge by Address Bits

A10	BA1	BA0	Precharge Bank(s)
LOW	LOW	LOW	Bank 0 only
LOW	LOW	HIGH	Bank 1 only
LOW	HIGH	LOW	Bank 2 only
LOW	HIGH	HIGH	Bank 3 only
HIGH	Don't Care	Don't Care	all banks

Burst Read Operation Followed by a Precharge

The following rules apply as long as the tRTP timing parameter - Internal Read to Precharge Command delay time - is less or equal two clocks, which is the case for operating frequencies less or equal 266 Mhz (DDR2 400 and 533 speed sorts):

Minimum Read to Precharge command spacing to the same bank = $AL + BL/2$ clocks. For the earliest possible precharge, the precharge command may be issued on the rising edge which is "Additive Latency (AL) + BL/2 clocks" after a Read Command, as long as the minimum tRAS timing is satisfied.

A new bank active command may be issued to the same bank if the following two conditions are satisfied simultaneously:

- (1) The RAS precharge time (tRP) has been satisfied from the clock at which the precharge begins.
- (2) The RAS cycle time (tRCmin) from the previous bank activation has been satisfied.

For operating frequencies higher than 266 MHz, tRTP becomes > 2 clocks and one additional clock cycle has to be added for the minimum Read to Precharge command spacing, which now becomes $AL + BL/2 + 1$ clocks.

Burst Read Operation Followed by Precharge: RL = 4 (AL = 1, CL = 3), BL = 4, tRTP ≤ 2 clocks

Burst Read Operation Followed by Precharge: RL = 4 (AL = 1, CL = 3), BL = 8, tRTP ≤ 2 clocks

Burst Read operation Followed by Precharge: RL=5(AL=2, CL=3), BL=4, tRTP<=2 clocks

Burst Read operation Followed by Precharge: RL=6(AL=2, CL=4), BL=4, tRTP<=2 clocks

Burst Read Operation Followed by Precharge: RL=4, (AL=0, CL=4), BL=8, tRTP>2 clocks

Burst Write followed by Precharge

Minimum Write to Precharge command spacing to the same bank = $WL + BL/2 + tWR$. For write cycles, a delay must be satisfied from the completion of the last burst write cycle until the Precharge command can be issued. This delay is known as a write recovery time (tWR) referenced from the completion of the burst write to the Precharge command. No Precharge command should be issued prior to the tWR delay, as DDR2 SDRAM does not support any burst interrupt by a Precharge command. tWR is an analog timing parameter (see the AC table in this datasheet) and is not the programmed value for tWR in the MRS.

Burst Write followed by Precharge : $WL = (RL - 1) = 3$, $BL = 4$, $tWR = 3$

Burst Write followed by Precharge : $WL = (RL - 1) = 4$, $BL = 4$, $tWR = 3$

Auto-Precharge Operation

Before a new row in an active bank can be opened, the active bank must be precharged using either the Precharge Command or the Auto-Precharge function. When a Read or a Write Command is given to the DDR2 SDRAM, the $\overline{\text{CAS}}$ timing accepts one extra address, column address A10, to allow the active bank to automatically begin precharge at the earliest possible moment during the burst read or write cycle. If A10 is low when the Read or Write Command is issued, then normal Read or Write burst operation is executed and the bank remains active at the completion of the burst sequence. If A10 is high when the Read or Write Command is issued, then the Auto-Precharge function is enabled. During Auto-Precharge, a Read Command will execute as normal with the exception that the active bank will begin to precharge internally on the rising edge which is CAS Latency (CL) clock cycles before the end of the read burst. Auto-Precharge is also implemented for Write Commands. The precharge operation engaged by the Auto-Precharge command will not begin until the last data of the write burst sequence is properly stored in the memory array. This feature allows the precharge operation to be partially or completely hidden during burst read cycles (dependent upon CAS Latency) thus improving system performance for random data access. The RAS lockout circuit internally delays the Precharge operation until the array restore operation has been completed so that the Auto-Precharge command may be issued with any read or write command.

Burst Read with Auto-Precharge

If A10 is high when a Read Command is issued, the Read with Auto-Precharge function is engaged. The DDR2 SDRAM starts an Auto-Precharge operation on the rising edge which is $(AL + BL/2)$ cycles later from the Read with AP command if $t_{RAS}(\text{min})$ and t_{RTP} are satisfied. If $t_{RAS}(\text{min})$ is not satisfied at the edge, the start point of Auto-Precharge operation will be delayed until $t_{RAS}(\text{min})$ is satisfied. If $t_{RTP}(\text{min})$ is not satisfied at the edge, the start point of Auto-precharge operation will be delayed until $t_{RTP}(\text{min})$ is satisfied. In case the internal precharge is pushed out by t_{RTP} , t_{RP} starts at the point where the internal precharge happens (not at the next rising clock edge after this event). So for $BL = 4$ the minimum time from Read with Auto-Precharge to the next Activate command becomes $AL + t_{RTP} + t_{RP}$. For $BL = 8$ the time from Read with Auto-Precharge to the next Activate command is $AL + 2 + t_{RTP} + t_{RP}$. Note that both parameters t_{RTP} and t_{RP} have to be rounded up to the next integer value. In any event internal precharge does not start earlier than two clocks after the last 4-bit prefetch.

A new bank active (command) may be issued to the same bank if the following two conditions are satisfied simultaneously:

- (1) The $\overline{\text{RAS}}$ precharge time (t_{RP}) has been satisfied from the clock at which the Auto-Precharge begins.
- (2) The $\overline{\text{RAS}}$ cycle time (t_{RC}) from the previous bank activation has been satisfied.

Burst Read with Auto-Precharge followed by an activation to the Same Bank (tRC Limit)

RL = 5 (AL = 2, CL = 3), BL = 4, tRTP ≤ 2 clocks

Burst Read with Auto-Precharge followed by an Activation to the Same Bank (tRAS Limit):

RL = 5 (AL = 2, CL = 3), BL = 4, tRTP ≤ 2 clocks

Burst Read with Auto-Precharge followed by an Activation to the Same Bank:

RL=4(AL=1, CL=3), BL=8, $t_{RTP} \leq 2$ clocks

Burst Read with Auto-Precharge followed by an Activation to the Same Bank:

RL=4(AL=1, CL=3), BL=8, $t_{RTP} > 2$ clocks

Burst Write with Auto-Precharge

If A10 is high when a Write Command is issued, the Write with Auto-Precharge function is engaged. The DDR2 SDRAM automatically begins precharge operation after the completion of the write burst plus the write recovery time delay (WR), programmed in the MRS register, as long as tRAS is satisfied. The bank undergoing Auto-Precharge from the completion of the write burst may be reactivated if the following two conditions are satisfied.

(1) The last data-in to bank activate delay time ($t_{DAL} = WR + t_{RP}$) has been satisfied.

(2) The RAS cycle time (t_{RC}) from the previous bank activation has been satisfied.

In DDR2 SDRAMs the write recovery time delay (WR) has to be programmed into the MRS mode register. As long as the analog twr timing parameter is not violated, WR can be programmed between 2 and 6 clock cycles. Minimum Write to Activate command spacing to the same bank = $WL + BL/2 + t_{DAL}$.

Examples:

Burst Write with Auto-Precharge (tRC Limit) : $WL = 2$, $t_{DAL} = 6$ ($WR = 3$, $t_{RP} = 3$), $BL = 4$

Burst Write with Auto-Precharge (WR+tRP Limit): WL=4, tDAL=6(WR=3, tRP=3), BL=4

Concurrent Auto-Precharge

DDR2 devices support the “concurrent Auto-Precharge” feature. A read with Auto-Precharge enabled, or a write with Auto-Precharge enabled, may be followed by any command to the other bank, as long as that command does not interrupt the read or write data transfer, and all other related limitations (e.g. contention between Read data and Write data must be avoided externally and on the internal data bus.

The minimum delay from a read or write command with Auto-Precharge enabled, to a command to a different bank, is summarized in the table below. As defined, the $WL = RL - 1$ for DDR2 devices which allows the command gap and corresponding data gaps to be minimized.

From Command	To Command (different bank, non-interrupting command)	Minimum Delay with Concurrent Auto-Pre- charge Support	Units
WRITE w/AP	Read or Read w/AP	$(CL - 1) + (BL/2) + tWTR$	tCK
	Write or Write w/AP	$BL/2$	tCK
	Precharge or Activate	1	tCK
Read w/AP	Read or Read w/AP	$BL/2$	tCK
	Write or Write w/AP	$BL/2 + 2$	tCK
	Precharge or Activate	1	tCK

Refresh

SDRAMs require a refresh of all rows in any rolling 64 ms interval. Each refresh is generated in one of two ways : by an explicit Auto-Refresh command, or by an internally timed event in Self-Refresh mode. Dividing the number of device rows into the rolling 64 ms interval defined the average refresh interval t_{REFI} , which is a guideline to controllers for distributed refresh timing. For example, a 512Mbit DDR2 SDRAM has 8192 rows resulting in a t_{REFI} of 7,8 μ s.

Auto-Refresh Command

Auto-Refresh is used during normal operation of the DDR2 SDRAMs. This command is nonpersistent, so it must be issued each time a refresh is required. The refresh addressing is generated by the internal refresh controller. This makes the address bits "Don't Care" during an Auto-Refresh command. The DDR2 SDRAM requires Auto-Refresh cycles at an average periodic interval of t_{REFI} (maximum).

When $\overline{CS}$, $\overline{RAS}$ and $\overline{CAS}$ are held low and $\overline{WE}$ high at the rising edge of the clock, the chip enters the Auto-Refresh mode. All banks of the SDRAM must be precharged and idle for a minimum of the Precharge time (t_{RP}) before the Auto-Refresh Command can be applied. An internal address counter supplies the addresses during the refresh cycle. No control of the external address bus is required once this cycle has started.

When the refresh cycle has completed, all banks of the SDRAM will be in the precharged (idle) state. A delay between the Auto-Refresh Command and the next Activate Command or subsequent Auto-Refresh Command must be greater than or equal to the Auto-Refresh cycle time (t_{RFC}).

To allow for improved efficiency in scheduling and switching between tasks, some flexibility in the absolute refresh interval is provided. A maximum of eight Auto-Refresh commands can be posted to any given DDR2 SDRAM, meaning that the maximum absolute interval between any Auto-Refresh command and the next Auto-Refresh command is $9 * t_{REFI}$.

Self-Refresh Command

The Self-Refresh command can be used to retain data, even if the rest of the system is powered down. When in the Self-Refresh mode, the DDR2 SDRAM retains data without external clocking.

The DDR2 SDRAM device has a built-in timer to accommodate Self-Refresh operation. The Self-Refresh Command is defined by having $\overline{CS}$, $\overline{RAS}$, $\overline{CAS}$ and $\overline{CKE}$ held low with $\overline{WE}$ high at the rising edge of the clock. ODT must be turned off before issuing Self Refresh command, by either driving ODT pin low or using EMRS command. Once the command is registered, $\overline{CKE}$ must be held low to keep the device in Self-Refresh mode. When the DDR2 SDRAM has entered Self-Refresh mode, all of the external control signals, except $\overline{CKE}$, are disabled. The clock is internally disabled during Self-Refresh Operation to save power. The user may change the external clock frequency or halt the external clock one clock after Self-Refresh entry is registered, how-ever, the clock must be restarted and stable before the device can exit Self-Refresh operation.

Once Self-Refresh Exit command is registered, a delay equal or longer than the t_{XSNR} or t_{XSRD} must be satisfied before a valid command can be issued to the device. $\overline{CKE}$ must remain high for the entire Self-Refresh exit period (t_{XSNR} or t_{XSRD}) for proper operation. NOP or DESELECT commands must be registered on each positive clock edge during the Self-Refresh exit interval. Since the ODT function is not supported during Self-Refresh operation, ODT has to be turned off before entering Self-Refresh Mode (t_{AOFD}) and can be turned on again when the t_{XSRD} timing is satisfied.

* = Device must be in the "All banks idle" state to entering Self Refresh mode.

ODT must be turned off prior to entering Self Refresh mode.

t_{XSRD} has to be satisfied for a Read or a Read with Auto-Precharge command.

t_{XSNR} has to be satisfied for any command except a Read or a Read with Auto-Precharge command.

Power-Down

Power-down is synchronously entered when CKE is registered low along with NOP or Deselect command. No read or write operation may be in progress when CKE goes low. These operations are any of the following: read burst or write burst and recovery. CKE is allowed to go low while any of other operations such as row activation, precharge or autoprecharge, mode register or extended mode register command time, or autorefresh is in progress. The DLL should be in a locked state when power-down is entered. Otherwise DLL should be reset after exiting power-down mode for proper read operation.

If power-down occurs when all banks are precharged, this mode is referred to as *Precharge Power-down*; if power-down occurs when there is a row active in any bank, this mode is referred to as *Active Power-down*. For *Active Power-down* two different power saving modes can be selected within the MRS register, address bit A12. When A12 is set to “low” this mode is referred as “standard active power-down mode” and a fast power-down exit timing defined by the tXARD timing parameter can be used. When A12 is set to “high” this mode is referred as a power saving “low power active power-down mode”. This mode takes longer to exit from the power-down mode and the tXARDS timing parameter has to be satisfied.

Entering power-down deactivates the input and output buffers, excluding CK, CK, ODT and CKE. Also the DLL is disabled upon entering precharge power-down or slow exit active power-down, but the DLL is kept enabled during fast exit active power-down. In power-down mode, CKE low and a stable clock signal must be maintained at the inputs of the DDR2 SDRAM, and all other input signals are “Don’t Care”. Power-down duration is limited by 9 times tREFI of the device.

The power-down state is synchronously exited when CKE is registered high (along with a NOP or Deselect command). A valid, executable command can be applied with power-down exit latency, tXP, tXARD or tXARDS, after CKE goes high. Power-down exit latencies are defined in the AC spec table of this data sheet.

Power-Down Entry

Active Power-down mode can be entered after an activate command. *Precharge Power-down mode* can be entered after a precharge, precharge-all or internal precharge command. It is also allowed to enter power-mode after an Auto-Refresh command or MRS / EMRS command when tMRD is satisfied.

Active Power-down mode entry is prohibited as long as a Read Burst is in progress, meaning CKE should be kept high until the burst operation is finished. Therefore Active Power-Down mode entry after a Read or Read with Auto-Precharge command is allowed after $RL + BL/2$ is satisfied.

Active Power-down mode entry is prohibited as long as a Write Burst and the internal write recovery is in progress. In case of a write command, active power-down mode entry is allowed when $WL + BL/2 + tWTR$ is satisfied.

In case of a write command with auto-precharge, power-down mode entry is allowed after the internal precharge command has been executed, which is $WL + BL/2 + WR$ starting from the write with auto-precharge command. In case the DDR2 SDRAM enters the *Precharge Power-down mode*.

Active Power-Down Mode Entry and Exit after an Activate Command

Active Power-Down Mode Entry and Exit after a Read Burst: RL = 4 (AL = 1, CL = 3), BL = 4

Active Power-Down Mode Entry and Exit after a Write Burst: $WL = 2$, $tWTR = 2$, $BL = 4$

Precharge Power Down Mode Entry and Exit

No Operation Command

The No Operation Command should be used in cases when the SDRAM is in a idle or a wait state. The purpose of the No Operation Command is to prevent the SDRAM from registering any unwanted commands between operations. A No Operation Command is registered when $\overline{CS}$ is low with $\overline{RAS}$, $\overline{CAS}$, and $\overline{WE}$ held high at the rising edge of the clock. A No Operation Command will not terminate a previous operation that is still executing, such as a burst read or write cycle.

Deselect Command

The Deselect Command performs the same function as a No Operation Command. Deselect Command occurs when $\overline{CS}$ is brought high, the $\overline{RAS}$, $\overline{CAS}$, and $\overline{WE}$ signals become don't care.

Input Clock Frequency Change

During operation the DRAM input clock frequency can be changed under the following conditions:

- During Self-Refresh operation
- DRAM is in precharged power-down mode and ODT is completely turned off.

The DDR2-SDRAM has to be in precharged power-down mode and idle. ODT must be already turned off and CKE must be at a logic "low" state. After a minimum of two clock cycles after t_{RP} and t_{AOFD} have been satisfied the input clock frequency can be changed. A stable new clock frequency has to be provided, before CKE can be changed to a "high" logic level again. After t_{XP} has been satisfied a DLL RESET command via EMRS has to be issued. During the following DLL re-lock period of 200 clock cycles, ODT must remain off. After the DLL-re-lock period the DRAM is ready to operate with the new clock frequency.

Clock Frequency Change in Precharge Power Down Mode

Asynchronous CKE Low Event

DRAM requires CKE to be maintained “high” for all valid operations as defined in this data sheet. If CKE asynchronously drops “low” during any valid operation DRAM is not guaranteed to preserve the contents of the memory array. If this event occurs, the memory controller must satisfy a time delay (t_{delay}) before turning off the clocks. Stable clocks must exist at the input of DRAM before CKE is raised “high” again. The DRAM must be fully re-initialized as described the the initialization sequence starting with step 4.

The DRAM is ready for normal operation after the initialization sequence. The minimum time clocks needs to be ON after CKE asynchronously drops low (the t_{delay} timing parameter) is equal to $t_{\text{IS}} + t_{\text{CK}} + t_{\text{IH}}$.

Asynchronous CKE Low Event

Truth Tables

Single Bank Precharge	H	H	L	L	H	L	BA	X	L	X	1, 2

1. All DDR2 SDRAM commands are defined by states of $\overline{CS}$, $\overline{WE}$, $\overline{RAS}$, $\overline{CAS}$, and CKE at the rising edge of the clock.

2. Bank addresses (BA0, BA1) determine which bank is to be operated upon. For (E)MRS BA selects an (Extended) Mode Register.

3. Burst reads or writes at BL = 4 cannot be terminated. See sections “Reads interrupted by a Read” and “Writes interrupted by a Write”.

4. The Power Down Mode does not perform any refresh operations. The duration of Power Down is therefore limited by the refresh requirements.

5. The state of ODT does not affect the states deccribed in this table. The ODT function is not available during Self Refresh.

6. “X” means “H or L (but a defined logic level)”.

7. Operation that is not specified is illegal and after such an event, in order to guarantee proper operation, the DRAM must be powered down and then restartet through the specified initialization sequence before normal operation can continue.

Clock enable (CKE) truth table for synchronous transitions

Current State ²	CKE		Command (N) ³ $\overline{\text{RAS}}, \overline{\text{CAS}}, \overline{\text{WE}}, \overline{\text{CS}}$	Action (N) ³	Notes
	Previous Cycle ¹ (N-1)	Current Cycle ¹ (N)			
Power Down	L	L	X	Maintain Power-Down	11, 13, 14
	L	H	DESELECT or NOP	Power Down Exit	4, 8, 11,13
Self Refresh	L	L	X	Maintain Self Refresh	11, 14,15
	L	H	DESELECT or NOP	Self Refresh Exit	4, 5, 9, 15
Bank(s) Active	H	L	DESELECT or NOP	Active Power Down Entry	4, 8, 10, 11, 13
All Banks Idle	H	L	DESELECT or NOP	Precharge Power Down Entry	4, 8, 10, 11,13
	H	L	REFRESH	Self Refresh Entry	6, 9, 11,13
	H	H	Refer to the Command Truth Table		7

NOTE 1 CKE (N) is the logic state of CKE at clock edge N; CKE (N-1) was the state of CKE at the previous clock edge.

NOTE 2 Current state is the state of the DDR2 SDRAM immediately prior to clock edge N.

NOTE 3 COMMAND (N) is the command registered at clock edge N, and ACTION (N) is a result of COMMAND (N).

NOTE 4 All states and sequences not shown are illegal or reserved unless explicitly described elsewhere in this document.

NOTE 5 On Self Refresh Exit DESELECT or NOP commands must be issued on every clock edge occurring during the t_{XSNR} period. Read commands may be issued only after t_{XSRD} (200 clocks) is satisfied.

NOTE 6 Self Refresh mode can only be entered from the All Banks Idle state.

NOTE 7 Must be a legal command as defined in the Command Truth Table.

NOTE 8 Valid commands for Power Down Entry and Exit are NOP and DESELECT only.

NOTE 9 Valid commands for Self Refresh Exit are NOP and DESELECT only.

NOTE 10 Power Down and Self Refresh can not be entered while Read or Write operations, (Extended) Mode Register Set operations or Precharge operations are in progress. See section Power-down and Self refresh operation for a detailed list of restrictions.

NOTE 11 t_{CKEmin} of 3 clocks means CKE must be registered on three consecutive positive clock edges. CKE must remain at the valid input level the entire time it takes to achieve the 3 clocks of registration. Thus, after any CKE transition, CKE may not transition from its valid level during the time period of $t_{\text{IS}} + 2 \times t_{\text{CK}} + t_{\text{IH}}$.

NOTE 12 The state of ODT does not affect the states described in this table. The ODT function is not available during Self Refresh.

NOTE 13 The Power Down does not perform any refresh operations. The duration of Power Down Mode is therefore limited by the refresh requirements outlined in Refresh command section.

NOTE 14 "X" means "don't care (including floating around VREF)" in Self Refresh and Power Down. However ODT must be driven HIGH or LOW in Power Down if the ODT function is enabled (Bit A2 or A6 set to "1" in EMR(1)).

NOTE 15 V_{REF} must be maintained during Self Refresh operation.

DM truth table

Name (Functional)	DM	DQs	Note
Write enable	L	Valid	1
Write inhibit	H	X	1
NOTE 1 Used to mask write data, provided coincident with the corresponding data			

Absolute Maximum DC Ratings

Symbol	Parameter	Rating	Units	Notes
VDD	Voltage on VDD pin relative to Vss	- 1.0 V ~ 2.3 V	V	1
VDDQ	Voltage on VDDQ pin relative to Vss	- 0.5 V ~ 2.3 V	V	1
VDDL	Voltage on VDDL pin relative to Vss	- 0.5 V ~ 2.3 V	V	1
V _{IN} , V _{OUT}	Voltage on any pin relative to Vss	- 0.5 V ~ 2.3 V	V	1
T _{STG}	Storage Temperature	-55 to +100	C	1

1. Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

AC & DC Operating Conditions

Recommended DC Operating Conditions (SSTL - 1.8)

Symbol	Parameter	Rating			Units	Notes
		Min.	Typ.	Max.		
VDD	Supply Voltage	1.7	1.8	1.9	V	
VDDL	Supply Voltage for DLL	1.7	1.8	1.9	V	4
VDDQ	Supply Voltage for Output	1.7	1.8	1.9	V	4
VREF	Input Reference Voltage	0.49*VDDQ	0.50*VDDQ	0.51*VDDQ	V	1.2
VTT	Termination Voltage	VREF-0.04	VREF	VREF+0.04	V	3

There is no specific device VDD supply voltage requirement for SSTL-1.8 compliance. However under all conditions VDDQ must be less than or equal to VDD.

1. The value of VREF may be selected by the user to provide optimum noise margin in the system. Typically the value of VREF is expected to be about 0.5 x VDDQ of the transmitting device and VREF is expected to track variations in VDDQ.
2. Peak to peak ac noise on VREF may not exceed +/-2% VREF (dc).
3. VTT of transmitting device must track VREF of receiving device.
4. VDDQ tracks with VDD, VDDL tracks with VDD. AC parameters are measured with VDD, VDDQ and VDDL tied together.

DC & AC Logic Input Levels

DDR2 SDRAM pin timing are specified for either single ended or differential mode depending on the setting of the EMRS "Enable $\overline{DQS}$ " mode bit; timing advantages of differential mode are realized in system design. The method by which the DDR2 SDRAM pin timing are measured is mode dependent. In single ended mode, timing relationships are measured relative to the rising or falling edges of DQS crossing at VREF. In differential mode, these timing relationships are measured relative to the crosspoint of DQS and its complement, $\overline{DQS}$. This distinction in timing methods is guaranteed by design and characterisation. In single ended mode, the DQS (and RDQS) signals are internally disabled and don't care.

Single-ended DC Input Levels

Symbol	Parameter	Min.	Max.	Units
V _{IH} (dc)	DC input logic high	VREF + 0.125	VDDQ + 0.3	V
V _{IL} (dc)	DC input logic low	- 0.3	VREF - 0.125	V

Single-ended AC Input Levels

Symbol	Parameter	DDR2-533		DDR2-667,800,1066		Units
		Min	Max	Min	Max	
V _{IH} (ac)	ac input logic high	VREF+0.250	-	VREF+0.200	-	V
V _{IL} (ac)	ac input logic low	-	VREF-0.250	-	VREF-0.200	V

Single-ended AC Input Test Conditions

Symbol	Condition	Value	Units	Notes
VREF	Input reference voltage	0.5 * VDDQ	V	1
VSWING(max)	Input signal maximum peak to peak swing	1.0	V	1
SLEW	Input signal minimum slew rate	1.0	V / ns	2, 3

1. Input waveform timing is referenced to the input signal crossing through the VREF level applied to the device under test.
2. The input signal minimum slew rate is to be maintained over the range from V_{IL}(dc)max to V_{IH}(ac)min for rising edges and the range from V_{IH}(dc)min to V_{IL}(ac)max for falling edges as shown in the below figure.
3. AC timings are referenced with input waveforms switching from V_{IL}(ac) to V_{IH}(ac) on the positive transitions and V_{IH}(ac) to V_{IL}(ac) on the negative transitions.

Differential DC and AC Input and Output Logic Levels

Symbol	Parameter	min.	max.	Units	Notes
VIN(dc)	DC input signal voltage	-0.3	VDDQ + 0.3		1
VID(dc)	DC differential input voltage	0.25	VDDQ + 0.6		2
VID(ac)	AC differential input voltage	0.5	VDDQ + 0.6	V	3
VIX(ac)	AC differential cross point input voltage	$0.5 * VDDQ - 0.175$	$0.5 * VDDQ + 0.175$	V	4
VOX(ac)	AC differential cross point output voltage	$0.5 * VDDQ - 0.125$	$0.5 * VDDQ + 0.125$	V	5

notes:

- 1) VIN(dc) specifies the allowable DC execution of each input of differential pair such as CK, $\overline{CK}$, DQS, $\overline{DQS}$, etc.
- 2) VID(dc) specifies the input differential voltage VTR - VCP required for switching. The minimum value is equal to VIH(dc) - VIL(dc).
- 3) VID(ac) specifies the input differential voltage VTR - VCP required for switching. The minimum value is equal to VIH(ac) - VIL(ac).
- 4) The value of VIX(ac) is expected to equal $0.5 \times VDDQ$ of the transmitting device and VIX(ac) is expected to track variations in VDDQ. VIX(ac) indicates the voltage at which differential input signals must cross.
- 5) The value of VOX(ac) is expected to equal $0.5 \times VDDQ$ of the transmitting device and VOX(ac) is expected to track variations in VDDQ. VOX(ac) indicates the voltage at which differential input signals must cross.

Capacitance Values

Parameter	Symbol	DDR2-533		DDR2-667		DDR2-800 DDR2-1066		Units
		Min	Max	Min	Max	Min	Max	
Input capacitance, CK and $\overline{CK}$	CCK	1.0	2.0	1.0	2.0	1.0	2.0	pF
Input capacitance delta, CK and $\overline{CK}$	CDCK	x	0.25	x	0.25	x	0.25	pF
Input capacitance, all other input-only pins	CI	1.0	2.0	1.0	2.0	1.0	1.75	pF
Input capacitance delta, all other input-only pins	CDI	x	0.25	x	0.25	x	0.25	pF
Input/output capacitance, DQ, DM, DQS, $\overline{DQS}$	CIO	2.5	4.0	2.5	3.5	2.5	3.5	pF
Input/output capacitance delta, DQ, DM, DQS, $\overline{DQS}$	CDIO	x	0.5	x	0.5	x	0.5	pF

Power and ground clamps are implemented on the following input only pins:

1. BA0-BA2
2. A0-A15
3. $\overline{\text{RAS}}$
4. $\overline{\text{CAS}}$
5. $\overline{\text{WE}}$
6. $\overline{\text{CS}}$
7. ODT
8. CKE

V-I Characteristics for input only pins with clamps

Voltage across clamp(V)	Minimum Power Clamp Current (mA)	Minimum Ground Clamp Current (mA)
0.0	0	0
0.1	0	0

Output Buffer Levels

Output AC Test Conditions

Symbol	Parameter	SSTL_18 Class II	Units	Notes
V_{OH}	Minimum Required Output Pull-up under AC Test Load	$V_{TT} + 0.603$	V	
V_{OL}	Maximum Required Output Pull-down under AC Test Load	$V_{TT} - 0.603$	V	
V_{OTR}	Output Timing Measurement Reference Level	$0.5 * V_{DDQ}$	V	1
1. The VDDQ of the device under test is referenced.				

Output DC Current Drive

Symbol	Parameter	SSTL_18 Class II	Units	Notes
$I_{OH(dc)}$	Output Minimum Source DC Current	- 13.4	mA	1, 3, 4
$I_{OL(dc)}$	Output Minimum Sink DC Current	13.4	mA	2, 3, 4
1. $V_{DDQ} = 1.7\text{ V}$; $V_{OUT} = 1420\text{ mV}$. $(V_{OUT} - V_{DDQ})/I_{OH}$ must be less than 21 ohm for values of V_{OUT} between V_{DDQ} and $V_{DDQ} - 280\text{ mV}$. 2. $V_{DDQ} = 1.7\text{ V}$; $V_{OUT} = 280\text{ mV}$. V_{OUT}/I_{OL} must be less than 21 ohm for values of V_{OUT} between 0 V and 280 mV. 3. The dc value of V_{REF} applied to the receiving device is set to V_{TT} 4. The values of $I_{OH(dc)}$ and $I_{OL(dc)}$ are based on the conditions given in Notes 1 and 2. They are used to test device drive current capability to ensure V_{IH} min plus a noise margin and V_{IL} max minus a noise margin are delivered to an SSTL_18 receiver. The actual current values are derived by shifting the desired driver operating point (see Section 3.3) along a 21 ohm load line to define a convenient driver current for measurement.				

Table 1. Full Strength Default Pulldown Driver Characteristics

Voltage (V)	Pulldown Current (mA)			
	Minimum (23.4 Ohms)	Nominal Default Low (18 ohms)	Nominal Default High (18 ohms)	Maximum (12.6 Ohms)

Figure 2. DDR2 Default Pullup Characteristics for Full Strength Output Driver

DDR2 SDRAM Default Output Driver V-I Characteristics

DDR2 SDRAM output driver characteristics are defined for full strength default operation as selected by the EMRS1 bits A7-A9 = '111'. Figures 1 and 2 show the driver characteristics graphically, and tables 1 and 2 show the same data in tabular format suitable for input into simulation tools. The driver characteristics evaluation conditions are:

Nominal Default 25°C (T case), VDDQ = 1.8V, typical process

Minimum 85°C (T case), VDDQ = 1.7 V, slow - slow process

Maximum 0°C (T case), VDDQ = 1.9V, fast - fast process

Default Output Driver Characteristic Curves Notes:

- 1) The full variation in driver current from minimum to maximum process, temperature, and voltage will lie within the outer bounding lines of the V-I curve of figures 1 and 2.
- 2) It is recommended that the "typical" IBIS V-I curve lie within the inner bounding lines of the V-I curves of figures 1 and 2.

Table 3. Full Strength Calibrated Pulldown Driver Characteristics

Voltage (V)	Calibrated Pulldown Current (mA)				
	Nominal Minimum (21 ohms)	Nominal Low (18.75 ohms)	Nominal (18 ohms)	Nominal High (17.2 ohms)	Nominal Maximum (15 ohms)
0.2	9.5	10.7	11.5	11.8	13.3
0.3	14.3	16.0	16.6	17.4	20.0
0.4	18.7	21.0	21.6	23.0	27.0

Table 4. Full Strength Calibrated Pullup Driver Characteristics

Voltage (V)	Calibrated Pullup Current (mA)				
	Nominal Minimum (21 ohms)	Nominal Low (18.75 ohms)	Nominal (18 ohms)	Nominal High (17.2 ohms)	Nominal Maximum (15 ohms)
0.2	-9.5	-10.7	-11.4	-11.8	-13.3
0.3	-14.3	-16.0	-16.5	-17.4	-20.0
0.4	-18.7	-21.0	-21.2	-23.0	-27.0

DDR2 SDRAM Calibrated Output Driver V-I Characteristics

Tables 3 and 4 show the data in tabular format suitable for input into simulation tools. The nominal points represent a device at exactly 18 ohms. The nominal low and nominal high values represent the range that can be achieved with a maximum 1.5 ohm step size with no calibration error at the exact nominal conditions only (i.e. perfect calibration procedure, 1.5 ohm maximum step size guaranteed by specification). Real system calibration error needs to be added to these values.

It must be understood that these V-I curves as represented here or in supplier IBIS models need to be adjusted to a wider range as a result of any system calibration error. Since this is a system specific phenomena, it cannot be quantified here. The values in the calibrated tables represent just the DRAM portion of uncertainty while looking at one DQ only. If the calibration procedure is used, it is possible to cause the device to operate outside the bounds of the default device characteristics tables and figures.

In such a situation, the timing parameters in the specification cannot be guaranteed. It is solely up to the system application to ensure that the device is calibrated between the minimum and maximum default values at all times. If this can't be guaranteed by the system calibration procedure, re-calibration policy, and uncertainty with DQ to DQ variation, then it is recommended that only the default values be used.

The nominal maximum and minimum values represent the change in impedance from nominal low and high as a result of voltage and temperature change from the nominal condition to the maximum and minimum conditions. If calibrated at an extreme condition, the amount of variation could be as much as from the nominal minimum to the nominal maximum or vice versa. The driver characteristics evaluation conditions are:

Nominal 25°C (T case), VDDQ = 1.8 V, typical process

Nominal Low and Nominal High 25°C (T case), VDDQ = 1.8 V, any process

Nominal Minimum 85°C (T case), VDDQ = 1.7 V, any process

Nominal Maximum 0°C (T case), VDDQ = 1.9 V, any process

IDD Specifications for DDR2-533/-667/-800/-1066

(VDDQ=1.8V±0.1V; VDD=1.8V±0.1V)

IDD Measurement Conditions

(VDDQ=1.8V±0.1V; VDD=1.8V±0.1V)

Symbol	Parameter/Condition
I _{DD0}	Operating Current - One bank Active - Precharge t _{RC} = t _{RCmin} , t _{CK} = t _{CKmin} ; Databus inputs are SWITCHING; Address and control inputs are SWITCHING, $\overline{CS}$ is HIGH between valid commands.
I _{DD1}	Operating Current - One bank Active - Read - Precharge One bank is accessed with t _{CK} = t _{CKmin} , t _{RC} = t _{RCmin} , t _{RAS} = t _{RASmin} , t _{RCD} = t _{RCDmin} , BL = 4, AL = 0, CL = CL _{min} ; Address and control inputs are SWITCHING, $\overline{CS}$ is HIGH between valid commands; I _{out} = 0 mA.
I _{DD2P}	Precharge Power-Down Current : all banks idle; $\overline{CS}$ is HIGH, CKE is LOW; t _{CK} = t _{CKmin} ; Data Bus inputs are FLOATING.
I _{DD2N}	Precharge Standby Current : all banks idle; $\overline{CS}$ is HIGH, CKE is HIGH; t _{CK} = t _{CKmin} ; Address and control inputs are SWITCHING; Data Bus inputs are SWITCHING.
I _{DD2Q}	Precharge Quiet Standby Current : all banks idle; $\overline{CS}$ is HIGH, CKE is HIGH; t _{CK} = t _{CKmin} ; Address and control inputs are STABLE; Data Bus inputs are FLOATING.
I _{DD3PF}	Active Power-Down Current : all banks open; CKE is LOW; t _{CK} = t _{CKmin} ; Address and control inputs are STABLE; Data Bus inputs are FLOATING; MRS A12 bit is set to "0" (Fast Power-down Exit).
I _{DD3PS}	Active Power-Down Current : all banks open; CKE is LOW; t _{CK} = t _{CKmin} ; Address and control inputs are STABLE; Data Bus inputs are FLOATING; MRS A12 bit is set to "1" (Slow Power-down Exit).
I _{DD3N}	Active Standby Current : all banks open; $\overline{CS}$ is HIGH, CKE is HIGH; t _{CK} = t _{CKmin} , t _{RAS} = t _{RASmin} , t _{RP} = t _{RPmin} ; Address and control inputs are SWITCHING; Data Bus inputs are SWITCHING.
I _{DD4R}	Operating Current - Burst Read : all banks active; continuous burst reads; t _{CK} = t _{CKmin} , t _{RAS} = t _{RASmin} , t _{RP} = t _{RPmin} ; BL = 4, AL = 0, CL = CL _{min} ; CKE is HIGH, $\overline{CS}$ is HIGH between valid commands; Address and control inputs are SWITCHING; Data Bus inputs are SWITCHING; I _{out} = 0 mA.
I _{DD4W}	Operating Current - Burst Write : all banks active; continuous burst writes; t _{CK} = t _{CKmin} , t _{RAS} = t _{RASmin} , t _{RP} = t _{RPmin} ; BL = 4, AL = 0, CL = CL _{min} ; CKE is HIGH, $\overline{CS}$ is HIGH between valid commands; Address and control inputs are SWITCHING; Data Bus inputs are SWITCHING; I _{out} = 0 mA.
I _{DD5B}	Burst Auto-Refresh Current : Refresh command at t _{RFC} = t _{RFCmin} , t _{CK} = t _{CKmin} ; $\overline{CS}$ is HIGH between valid commands.
I _{DD6}	Self-Refresh Current : CKE = 0.2V; external clock off, CK and $\overline{CK}$ at 0V; Address and control inputs are FLOATING; Data Bus inputs are FLOATING.
I _{DD7}	Operating Bank Interleave Read Current : 1. All banks interleaving reads, BL = 4, CL = CL _{min} , AL = t _{RCDmin} - 1 x t _{CKmin} , t _{CK} = t _{CKmin} , t _{RC} = t _{RCmin} , t _{RRD} = t _{RRDmin} , t _{RCD} = 1 x t _{CKmin} ; CKE is HIGH, $\overline{CS}$ is HIGH between valid commands; I _{out} = 0 mA. Address and control inputs are stable during DESELECT; Data Bus inputs are SWITCHING. 2. Timing pattern : - DDR2 -400 (200Mhz, CL=3) : t _{ck} = 5 ns, BL = 4, t _{RCD} = 3 * t _{ck} , AL = 2 * t _{ck} , t _{RC} = 12 * t _{ck} Read : A0 RA0 A1 RA1 A2 RA2 A3 RA3 D D D D - DDR2 -533 (266Mhz, CL=4) : t _{ck} = 3.7 ns, BL = 4, t _{RCD} = 4 * t _{ck} , AL = 3 * t _{ck} , t _{RC} = 16 * t _{ck} Read : A0 RA0 D A1 RA1 D A2 RA2 D A3 RA3 D D D D - DDR2 -667 (333Mhz, CL=5) : t _{ck} = 3 ns, BL = 4, t _{RCD} = 5 * t _{ck} , AL = 4 * t _{ck} , t _{RC} = 20 * t _{ck} Read : A0 RA0 D D A1 RA1 D D A2 RA2 D D A3 RA3 D D D D - DDR2 -800 (400Mhz, CL=5) : t _{ck} = 2.5 ns, BL = 4, t _{RCD} = 5 * t _{ck} , AL = 4 * t _{ck} , t _{RC} = 23 * t _{ck} Read : A0 RA0 D D A1 RA1 D D A2 RA2 D D A3 RA3 D D D D D D D D
1. Data Bus consisis of DQ, DM, DQS, $\overline{DQS}$, RDQS, $\overline{RDQS}$, LDQS, $\overline{LDQS}$, UDQS and $\overline{UDQS}$. 2. Definition for IDD : LOW is defined as VIN ≤ VILAC(max.); HIGH is defined as VIN ≥ VIHAC(min.); STABLE is defined as inputs are stable at HIGH or LOW level FLOATING is defined as inputs are VREF SWITCHING is defined as inputs are changing between HIGH and LOW every other clock for address and control signals, and inputs changing 50% of each data transfer for DQ signals. 3. Legend : A=Activate, RA=Read with Auto-Precharge, D=DESELECT

Notes for Electrical Characteristics & AC Timing

1. Input slew rate is 1 V/ns and AC timings are guaranteed for linear signal transitions.
For other slew rates see the derating tables on the next pages.
2. The $\overline{\text{CK}}$ / $\overline{\text{CK}}$ input reference level (for timing reference to $\overline{\text{CK}}$ / $\overline{\text{CK}}$) is the point at which $\overline{\text{CK}}$ and $\overline{\text{CK}}$ cross:
the $\overline{\text{DQS}}$ / $\overline{\text{DQS}}$ input reference level is the crosspoint when in differential strobe mode; the input reference level for signals other than $\overline{\text{CK}}$ / $\overline{\text{CK}}$, or $\overline{\text{DQS}}$ / $\overline{\text{DQS}}$ is VREF.
3. Inputs are not recognized as valid until VREF stabilizes. During the period before VREF stabilizes, CKE = 0.2 x VDDQ is recognized as LOW.
4. The output timing reference voltage level is VTT.
5. Min (tCL, tCH) refers to the smaller of the actual clock low time and the actual clock high time as provided to the device (i.e. this value can be greater than the minimum specification limits for tCL and tCH).
6. For input frequency change during DRAM operation.
7. tHZ and tLZ transitions occur in the same access time windows as valid data transitions. These parameters are not referred to a specific voltage level, but specify when the device is no longer driving (HZ), or begins driving (LZ).
8. These parameters guarantee device timing, but they are not necessarily tested on each device.
9. The specific requirement is that $\overline{\text{DQS}}$ and $\overline{\text{DQS}}$ be valid (HIGH, LOW, or some point on a valid transition) on or before this $\overline{\text{CK}}$ edge. A valid transition is defined as monotonic and meeting the input slew rate specifications of the device. When no writes were previously in progress on the bus, $\overline{\text{DQS}}$ will be transitioning from Hi-Z to logic LOW. If a previous write was in progress, $\overline{\text{DQS}}$ could be HIGH, LOW, or transitioning from HIGH to LOW at this time, depending on tDQSS. When programmed in differential strobe mode, $\overline{\text{DQS}}$ is always the logic complement of $\overline{\text{DQS}}$ except when both are in high-Z.
10. The maximum limit for this parameter is not a device limit. The device operate with a greater value for this parameter, but system performance (bus turnaround) degrades accordingly.
11. A maximum of eight Auto-Refresh commands can be posted to any given DDR2 SDRAM device.
(Note : tRFC depends on DRAM density)
12. For each of the terms, if not already an integer, round to the next highest integer. tCK refers to the application clock period. WR refers to the WR parameter stored in the MRS.
13. tWTR is at least two clocks independent of operation frequency.
14. User can choose two different active power-down modes for additional power saving via MRS address bit A12.
In "standard active power-down mode" (MRS, A12 = "0") a fast power-down exit timing tXARD can be used.
In "low active power-down mode" (MRS, A12 = "1") a slow power-down exit timing tXARDS has to be satisfied.
15. Timings are guaranteed with command / address input slew rate of 1.0 V/ns.
16. Timings are guaranteed with data / mask input slew rate of 1.0 V/ns.
See Specific Notes on derating for other slew values.
17. Timings are guaranteed with $\overline{\text{CK}}$ / $\overline{\text{CK}}$ differential slew rate 2.0 V/ns, and $\overline{\text{DQS}}$ / $\overline{\text{DQS}}$ (and $\overline{\text{RDQS}}$ / $\overline{\text{RDQS}}$) differential slew rate 2.0 V/ns in differential strobe mode. and a slew rate of 1 V/ns in single ended mode.
See Specific Notes on derating for other slew values.

18. Data setup and hold time derating.

DDR2-400/533 tDS/tDH derating with differential data strobe

19. If refresh timing or tDS / tDH is violated, data corruption may occur and the data must be re-written with valid data before a valid READ can be executed.

20. In all circumstances, tXSNR can be satisfied using tXSNR = tRFC + 10 ns.

21. The tRCD timing parameter is valid for both activate command to read or write command with and without Auto-Precharge. Therefore a separate parameter tRAP for activate command to read or write command with Auto-Precharge is not necessary anymore.

22. tRAS(max) is calculated from the maximum amount of time a DDR2 device can operate without a Refresh command which is equal to 9 * tREFI.

Reference Loads, Slew Rates and Slew Rate Derating

Reference Load for Timing Measurements

The figure represents the timing reference load used in defining the relevant timing parameters of the device. It is not intended to either a precise representation of the typical system environment nor a depiction of the actual load presented by a production tester. System designers will use IBIS or other simulation tools to correlate the timing reference load to a system environment. This load circuit is also used for output slew rate measurements.

Slew Rate Measurements

Output Slew Rate

Output slew rate is characterized under the test conditions as shown in the figure below

Output slew rate for falling and rising edges is measured between $V_{TT} - 250$ mV and $V_{TT} + 250$ mV for single ended signals. For differential signals (e.g. $DQS - \overline{DQS}$) output slew rate is measured between $DQS - \overline{DQS} = -500$ mV and $DQS - \overline{DQS} = +500$ mV. Output slew rate is guaranteed by design, but is not necessarily tested on each device.

Input Slew Rate

Input slew for single ended signals is measured from dc-level to ac-level from $V_{REF} - 125$ mV to $V_{REF} + 250$ mV for rising edges and from $V_{REF} + 125$ mV to $V_{REF} - 250$ mV for falling edges.

For differential signals (e.g. $CK - \overline{CK}$) slew rate for rising edges is measured from $CK - \overline{CK} = -250$ mV to $CK - \overline{CK} = +500$ mV (250 mV to -500 mV for falling edges). Test conditions are the same as for timing measurements.

Overshoot and Undershoot Specification

AC Overshoot / Undershoot Specification for Address and Control Pins

Parameter	DDR2-533	DDR2-667	DDR2-800	DDR2-1066	Unit
Maximum peak amplitude allowed for overshoot area	0.9	0.9	0.9	0.5(0.9) ¹	V
Maximum peak amplitude allowed for undershoot area	0.9	0.9	0.9	0.5(0.9) ¹	V
Maximum overshoot area above VDDQ	1.00	0.80	0.66	0.5	V.ns
Maximum undershoot area below VSSQ	1.00	0.80	0.66	0.5	V.ns

Note 1 The maximum requirements for peak amplitude were reduced from 0.9V to 0.5V. Register vendor datasheet will specify the maximum over/undershoot induced in specific RDIMM applications. DRAM vendor datasheet will also specify the maximum overshoot/undershoot that their DRAM can tolerate. This will allow the RDIMM supplier to understand whether the DRAM can tolerate the overshoot that the register will induce in the specific RDIMM application.

AC Overshoot / Undershoot Specification for Clock, Data, Strobe and Mask Pins

Parameter	DDR2-533	DDR2-667	DDR2-800	DDR2-1066	Unit
Maximum peak amplitude allowed for overshoot area	0.5	0.5	0.5	0.5	V
Maximum peak amplitude allowed for undershoot area	0.5	0.5	0.5	0.5	V
Maximum overshoot area above VDDQ	0.28	0.23	0.23	0.19	V.ns
Maximum undershoot area below VSSQ	0.28	0.23	0.23	0.19	V.ns
